Abstract:
The aerial parts of Zygophyllum album L. are used in folk medicine as an anti-diabetic agent and as a drug active against several pathologies. In this work we present the chemical composition of Algerian phenolic extracts obtained by different solvents and extraction methods.
The phytochemical study was based on a colometer method, Phenolic compound content and LC/ESI-MS analyses.
The methanolic extract of zygophyllum album was at least the best extract studied for its quantitative and qualitative richness in phenolic compounds.
All Z.album extracts and specially the methanolic one are a promising source of health products for functional food or nutraceutical industries.

Keywords:
Zygophyllum Album; Folk Medicine; Anti-Diabetic Agent.

1. INTRODUCTION

They are some works done which aimed at knowing the different antimicrobial and phytochemical constituents of medicinal plants. Zygophyllum album L. is one of the large world of benefits plants belongs to Zygophyllaceae family, genus Zygophyllum. Four species of Zygophyllum are recorded in Algeria [1].

The use of plants in the form of crude extracts, infusions and plasters is a widespread practice in the treatment of number of pathologies. Local surveys show that Zygophyllum album L. is used against aches and for calm thirst. It is also used for wound care, treatment of dental caries, and washing clothes and hair. The buds are used in infusions for face care [2]. As an alternative, the scientific research of plants used in traditional medicine is receiving growing interest as away of identifying new phytomedicinal agents[3]. Some phytochemical data on Z. album have been reported [4],although the chemical composition and biological activities of Z. album have not
been fully elucidated. So the objective of the present study was to develop a fast and reliable method to determine the chemical composition of the alcoholic extracts of the aerial parts of fresh *Z. album* L.

2. MATERIALS AND METHODS

2.1. PLANT MATERIAL

Fresh upper parts from *Zygophyllum album* (leaves, flowers and stems) were collected in April during the flowering stage 2014 from SidiKhouiled region, Sahara of Ouargla, Algeria. The sampling was done by a randomized collection of 15–20 sub-shrubs in an area of about 200 m² each areal parts of *Z. album* were isolated manually in our laboratory to obtain a weight of 500–700 g of each part. Botanical identification of this species was carried out according to Africain flowering plants database and by local experts.

2.2. CHEMICAL AND REAGENTS

Folin–Ciocalteu reagent, anhydrous sodium carbonate (Na₂CO₃), gallic acid, sodium nitrite (NaNO₂) solution, aluminium chloride hexahydrate solution (AlCl₃, 6H₂O), and vanillin were purchased from Fluka (Buchs, Switzerland). Sulphuric acid (H₂SO₄) was obtained from Merck (Darmstadt, Germany).

The solvents were purchased from Sigma–Aldrich (Oakville, ON). All other chemical reagents were purchased from Sigma–Aldrich (Oakville, ON) or AlfaAesar Co. (Ward Hill, MA) and were used as received.

2.3. POLYPHENOLS EXTRACTION

The plant material was dried at ambient temperature and stored in a dry place prior to use. The plant was washed well with water, dried at room temperature in the dark, and then ground in an electric grinder to give a coarse powder. In this study, samples were extracted by decoction (10%), maceration with ethanol (8%) and by extraction with solvents of increasing polarity (Dichloromethan and methanol/soxhlet) methods.[5,6].

2.4. PHYTOCHEMICAL SCREENING BY COLOMETER METHOD

All plant extract were tested for the presence of different families of compounds according to methods reviously described [7,8].

2.5. POLYPHENOLS ANALYSIS

The total phenolic in extracts content was determined by spectrometry using “Folin-Ciocalteu” reagent assay [9]. Gallic acid was used as a standard for the calibration curve. The total phenolic content was expressed as milligrams of gallic acid equivalents per gram of dry weight (mg GAE/g DW).
2.6. CONDENSED TANNIN CONTENT

Condensed tannins were transformed by the reaction with vanillin to anthocyanidols. Condensed tannin contents of each organ (three replicates per treatment) were expressed as mg catechin equivalents per gram (mg CE/g) through the calibration curve with catechin.

2.7. TOTAL FLAVONOID CONTENT

Total flavonoid content was measured according to [10]. Total flavonoid contents were expressed as mg catechin equivalents per gram (mg CE/g).

2.8. TOTAL ANTHOCYANS CONTENT

Total anthocyan content was evaluated by colorimetry using a UV-visible spectrophotometer. The concentration of anthocyanin pigment in the extract is expressed in mg equivalent cyanidin-3-glucose per liter of solution or mg of cyanidin-3 equivalent glucose / g dry matter (Cg / g dM) [11].

2.9. LC/ESI-MS ANALYSES

The LC analyses were conducted using a Prominence Liquid Chromatograph (Shimadzu, Kyoto, Japan) equipped with an SLC-10A controller, LC-20AD pump, SIL-10AF auto sampler, and SPDM10A PDA detector. A Phenomenex Luna C-18(2) column (250 x 4.6 mm, 5 mm) was used. The mobile phase consisted of methanol (A) and acetonitrile (B) at a flow rate of 0.8 mL min⁻¹ using the following gradients: 0.1–23 min, 10–40% of solvent B in A; 23.01–40 min, 10% solvent B and 90% solvent A.

The detection was done on a DAD detector set at 340 nm. The mobile phase was prepared daily, filtered through a 0.45 mm membrane filter (Millipore), and sonicated before use [12]. The system was optimized in the positive mode for anthocyanins and in negative for the other phenolic compounds.

The flow-rate used was 0.4 ml/min. LC/MS accurate mass spectra were recorded across the range 100–3000 m/z. The DAD detector was set to a scanning range of 200–400 nm. The phenolic compounds were identified mainly by their UV-spectra and ESI/MS spectra and by comparing with published data [13].
3. RESULTS AND DISCUSSION

3.1. EXTRACTION YIELDS

According to the results we were able to observe more or less considerable yields were observed in the aqueous, dichloromethane and methanolic extracts of *Z. album* which are of the order of 15, 14.6 and 14.5%, respectively[14,9]. In contrast, the yield of ethanol extract was the lowest other recorded returns.

Generally, plant diversity is responsible for the wide variability of physico-chemical properties influencing the extraction of polyphenols [15]. Among other things, the solubility of phenolic compounds is affected by the polarity of the solvent used. Consequently, it is very difficult to develop an extraction process suitable for the extraction of all phenolic compounds from the plant [16,17].

3.2. RESULTS OF PHYTOCHEMICAL SCREENING

Table 1: Results of phytochemical screening

Aq.E: aqueous extract; EtOH.E: ethanolic extract; DCM.E: dichloromethan extract; MeOH.E: methanolic extract
These tests are related to the intensity of the precipitate and turbidity or the color is proportional to the amount of the desired substance. So:

- A positive reaction is represented by: +++
- A moderately positive reaction is represented by: ++
- A weakly positive reaction is represented by: +
- The absence of the substance is represented by: -.

Preliminary evaluation of the phytochemical composition of the extracts from the aerial part of *Z. album* gave results summarized in Table 01 where several families of phenolic compounds are present. In fact, these results show that the methanolic extract of the plant is very rich in saponins, heteroside, anthocyanins and flavonoids. There is also a small amount of tannins and alkaloids. Similar results were found in the studies of [18] on secondary metabolites of the methanol extract of *Zygophyllum cornutum coss.*

The work of [13] demonstrated the absence of free anthracene derivatives and anthraquinones in the *Z. album* species, which is consistent with our results. On the other hand, the presence of flavonoids in the tested plants is lower compared to that found in the studies of [19] on the same species from Egypt.

In general, extraction is a very important step before the quantitative and qualitative analysis itself. It is influenced by the extraction method chosen according to the phytochemicals to be studied. Other factors, such as pH, temperature, material volume to solvent volume ratio, time intervals, number and individual extraction steps, also play an important role in the quantification variation of the compounds.

<sup>a</sup>mg acid galic equivalent/g dry weight. <sup>b</sup>c: mg catech in equivalent/g dry weight. <sup>c</sup>d: cyanidin-3 glucose/g dry weight (All values are the average of three repeats ± standard deviation)
Based on the results obtained in Table 02 and figure 02, there was a marked difference in the polyphenol content, but this does not preclude the highest polyphenol content recorded in The aqueous and methanolic extract (10.83 ± 0.601, 6.766 ± 0.628 mg GAE / g), these results are comparable to those found by [9] for aqueous extract and[13] for methanolic extract, but both remain significantly higher than the results found by[20] on the same species from the same region which is Sahara de Ouergla.

For flavonoids, tannins and anthocyanins, the values obtained are generally low, but compared with other studies, we find that our results are higher than those recorded by [20] and more or less close to the values recorded by [21] on ethanolic and methanolic extracts of *Z. hamiense* from the Sahara of Muhaisnah in Dubai. However, it is difficult to compare our results with those of the bibliography, as several factors may influence the qualitative and quantitative distribution of phenolic compounds in our extracts, mainly climatic and environmental factors: geographical area, drought, soil. [22] and the harvesting period, stage of development and part of the plant used[23], and the method of extraction and quantification. The selectivity of the solvent used can also influence the total polyphenol and flavonoid content [24].

</tbody>
</table>
The content of phenolic compounds obtained by LC/MS is shown in Figure 2 and table 3. Nine compounds were identified under the analytical conditions used, of which three constitute the major proportion:
- Isorhamnetin-3-O-rutinoside (11), Malvidin 3-rhamnoside (9), Quercitin-3-sulphate (6) and kaempferol 3-O-rutinoside (10) (table 3).
- The negative ion mass spectrum exhibited [M-H] at m/z 623.3, which makes it possible to propose the chemical formula C_{28}H_{32}O_{16}. Isorhamnetin-3-O-rutinoside is one of the main phenolic compounds in this species; it corresponds to that previously isolated from the Egyptian species of Z. album. This compound appears to be a chemo-taxonomic marker in the genus Zygophyllum[13].
- The flavonoic compounds (9) (m/z 482.4 C_{23}H_{25}O_{11}) are temporarily determined in this species for the second time after the study of [25]. The remaining two (6) and (10), they were already identified and described several times by[19,25]. Furthermore, two compounded triterpenoidsaponins (12 and 15) with ions [MH] at m/z 809.4 (C_{42}H_{66}O_{13}), 873.4 (C_{42}H_{66}O_{17}S) were respectively identified in this species, Zygophyloside K (12) previously isolated and described from Z. album and decumbens[13,25]. Zygophyloside F (15) was previously described by [26,25,27].

4. CONCLUSION

In conclusion, these results have established that Z. album is a true source of phenolic compounds which disperse according to the mode and the extraction solvent. These data suggest this medicinal halophyte might be a valuable source of bioactive secondary metabolites such as triterpenoidsaponins, sterol and flavonoids with beneficial properties, and a promising source of health products for functional food or nutraceutical industries.
